<u>**เอกสารกำกับยาสำหรับแพทย์ภาษาอังกฤษ**</u>

SIRTURO™

FULL PRESCRIBING INFORMATION

WARNING: INCREASED MORTALITY and QT PROLONGATION
<u>**Increased Mortality**</u>
- **An increased risk of death was seen in the SIRTURO treatment group (9/79, 11.4%) compared to the placebo treatment group (2/81, 2.5%) in one placebo-controlled trial in adults. Only use SIRTURO in patients 12 years of age and older when an effective treatment regimen cannot otherwise be provided *[see (4.4.1)]*.**

<u>**QT Prolongation**</u>
- **QT prolongation can occur with SIRTURO. Use with drugs that prolong the QT interval may cause additive QT prolongation. Monitor ECGs. Discontinue SIRTURO if significant ventricular arrhythmia or if QTcF interval prolongation of greater than 500 ms develops *[see (4.4.2)]*.**

---

1. **Name of the Medicinal Product**
   1.1 **Product Name**
       SIRTURO
   1.2 **Strength**
   100mg
   1.3 **Pharmaceutical Dosage Form**
       Tablets
2. **Qualitative and Quantitative Composition**
   2.1 **Qualitative Declaration**
       Bedaquiline fumarate is a white to almost white powder and is practically insoluble in aqueous media. The chemical name of bedaquiline fumarate is (1R, 2S)-1-(6-bromo-2-methoxy-3-quinolinyl)-4-(dimethylamino)-2-(1-naphthalenyl)-1-phenyl-2-butanol compound with fumaric acid (1:1). It has a molecular formula of $C_{32}H_{31}BrN_2O_2 \bullet C_4H_4O_4$ and a molecular weight of 671.58 (555.50 + 116.07). The molecular structure of bedaquiline fumarate is the following:
   SIRTURO (bedaquiline) contains the following inactive ingredients: colloidal silicon dioxide, corn starch, croscarmellose sodium, hypromellose 2910 15 mPa.s, lactose monohydrate, magnesium stearate, microcrystalline cellulose, polysorbate 20, purified water (removed during processing).

   2.2 **Quantitative Declaration**

SIRTURO (bedaquiline) is a diarylquinoline antimycobacterial drug containing bedaquiline as the fumarate salt. SIRTURO is available as 100 mg strength tablets for oral administration. Each tablet contains 100 mg of bedaquiline (equivalent to 120.89 mg of bedaquiline fumarate).

3. Pharmaceutical Form

SIRTURO tablets, 100 mg are uncoated white to almost white round biconvex with debossing of "T" over "207" on one side and "100" on the other side.

4. Clinical Particulars

4.1 Therapeutic indication

SIRTURO is a diarylquinoline antimycobacterial drug indicated as part of combination therapy in the treatment of adult and pediatric patients (12 to less than 18 years of age and weighing at least 30 kg) with pulmonary multi-drug resistant tuberculosis (MDR-TB). Reserve SIRTURO for use when an effective treatment regimen cannot otherwise be provided.

Limitations of Use:

- Do not use SIRTURO for the treatment of:

  o Latent infection due to *Mycobacterium tuberculosis*
  o Drug-sensitive tuberculosis
  o Extra-pulmonary tuberculosis
  o Infections caused by non-tuberculous mycobacteria

- The safety and efficacy of SIRTURO in the treatment of HIV infected patients with MDR-TB have not been established as clinical data are limited *[see Clinical Studies]*.

4.2 Posology and method of administration

4.2.1 Important Administration Instructions

- Administer SIRTURO by directly observed therapy (DOT).
- Use SIRTURO only in combination with other anti-mycobacterial drugs *[see Posology and method of administration (4.2.3)]*.
- Emphasize the need for compliance with full course of therapy.

4.2.2 Required Testing Prior to Administration

Prior to treatment with SIRTURO, obtain the following:

- Susceptibility information for the background regimen against *M. tuberculosis* isolate if possible *[see Posology and method of administration (4.2.1)]*
- ECG *[see Special Warnings and Precautions (4.4.2)]*
- Serum potassium, calcium, and magnesium concentrations *[see Special Warnings and Precautions (4.4.2)]*
- Liver enzymes *[see Special Warnings and Precautions (4.4.4)]*

4.2.3 Recommended Dosage in Combination Therapy

Only use SIRTURO in combination with at least 3 other drugs to which the patient's MDR-TB isolate has been shown to be susceptible *in vitro*. If *in vitro* testing results are unavailable, SIRTURO treatment may be initiated in combination with at least 4 other drugs to which the patient's MDR-TB isolate is likely to be susceptible. Refer to the prescribing information of the drugs used in combination with SIRTURO.

See Table 1 for the recommended dosage of SIRTURO in adult and pediatric patients (12 to less than 18 years of age).

Table 1:   Recommended Dosage of SIRTURO

Population	Dosage
Adult patients (18 years of age and older)	400 mg orally once daily for the first two weeks, followed by 200 mg orally three times per week (with at least 48 hours between doses) for 22 weeks (total duration of 24 weeks)
Pediatric patients (12 to less than 18 years of age) and weighing at least 30 kg	

The SIRTURO tablet should be swallowed whole with water and taken with food.

If a dose is missed during the first 2 weeks of treatment, do not administer the missed dose (skip the dose and then continue the daily dosing regimen). From Week 3 onwards, if a 200 mg dose is missed, administer the missed dose as soon as possible, and then resume the 3 times a week dosing regimen.

4.2.4 Pediatric Use

The safety and effectiveness of SIRTURO have been established in pediatric patients 12 to less than 18 years of age and weighing at least 30 kg. The use of SIRTURO in this pediatric population is supported by evidence from the study of SIRTURO in adults together with additional pharmacokinetic and safety data from the single-arm, open-label, trial that enrolled 15 pediatric patients 14 to less than 18 years of age with confirmed or probable MDR-TB infection who were treated with SIRTURO for 24 weeks in combination with a background regimen *[see Undesirable effects (4.8), Pharmacokinetic Properties (5.2) and Clinical Studies]*. The use of SIRTURO in pediatric patients 12 to less than 14 years of age is based on information obtained from the studies conducted in adults and pediatric patients 14 to less than 18 years of age *[see Undesirable effects (4.8) and Clinical Studies]*.

The safety and effectiveness of SIRTURO in pediatric patients less than 12 years of age and/or weighing less than 30 kg have not been established.

4.2.5 Geriatric Use

Because of limited data, differences in outcomes or specific risks with SIRTURO cannot be ruled out for patients 65 years of age and older.

4.2.6 Hepatic Impairment

The pharmacokinetics of bedaquiline were assessed after single-dose administration to adult patients with moderate hepatic impairment (Child-Pugh B) *[see Pharmacokinetic Properties (5.2)]*. Based on these results, no dose adjustment is necessary for SIRTURO in patients with mild or moderate hepatic impairment. SIRTURO has not been studied in patients with severe hepatic impairment and should be used with caution in these patients only when the benefits outweigh the risks. Clinical monitoring for SIRTURO-related adverse reactions is recommended *[see Special Warnings and Precautions (4.4.4)]*.

4.2.7 Renal Impairment

SIRTURO has mainly been studied in adult patients with normal renal function. Renal excretion of unchanged bedaquiline is not substantial (less than or equal to 0.001%). No dose adjustment is required in patients with mild or moderate renal impairment. In patients with severe renal impairment or end stage renal disease requiring hemodialysis or peritoneal dialysis, SIRTURO should be used with caution *[see Pharmacokinetic Properties (5.2)]*. Monitor adult and pediatric patients for adverse reactions of SIRTURO when administered to patients with severe renal impairment or end stage renal disease requiring hemodialysis or peritoneal dialysis.

4.3 Contraindication
None

4.4 Special warning and precautions
4.4.1 Increased Mortality
An increased risk of death was seen in the SIRTURO treatment group (9/79, 11.4%) compared to the placebo treatment group (2/81, 2.5%) in one placebo-controlled trial in adults (based on the 120-week visit window). One death occurred during the 24 weeks of administration of SIRTURO. The imbalance in deaths is unexplained. No discernible pattern between death and sputum culture conversion, relapse, sensitivity to other drugs used to treat tuberculosis, HIV status, or severity of disease could be observed. Only use SIRTURO in patients 12 years of age and older when an effective treatment regimen cannot otherwise be provided *[see Undesirable effects (4.8)]*.

4.4.2 QT Prolongation
SIRTURO prolongs the QT interval. Obtain an ECG before initiation of treatment, and at least 2, 12, and 24 weeks after starting treatment with SIRTURO. Obtain serum potassium, calcium, and magnesium at baseline and correct if abnormal. Monitor electrolytes if QT prolongation is detected *[see Undesirable effects (4.8)* and *Interaction with other medicinal products and other forms of interactions (4.5)]*. SIRTURO has not been studied in patients with ventricular arrhythmias or recent myocardial infarction.

The following may increase the risk for QT prolongation when patients are receiving SIRTURO:
- use with other QT prolonging drugs including fluoroquinolones and macrolide antibacterial drugs and the antimycobacterial drug, clofazimine
- a history of Torsade de Pointes
- a history of congenital long QT syndrome
- a history of or ongoing hypothyroidism

- a history of or ongoing bradyarrhythmias
- a history of uncompensated heart failure
- serum calcium, magnesium, or potassium levels below the lower limits of normal

If necessary, bedaquiline treatment initiation could be considered in these patients after a favorable benefit risk assessment and with frequent ECG monitoring.

Discontinue SIRTURO and all other QT prolonging drugs if the patient develops:
- Clinically significant ventricular arrhythmia
- A QTcF interval of greater than 500 ms (confirmed by repeat ECG)

If syncope occurs, obtain an ECG to detect QT prolongation.

4.4.3 Risk of Development of Resistance to Bedaquiline
A potential for development of resistance to bedaquiline in *M. tuberculosis* exists *[see Microbiology]*. Bedaquiline must only be used in an appropriate combination regimen for the treatment of pulmonary MDR-TB to reduce the risk of development of resistance to bedaquiline *[see Therapeutic indication (4.1)]*.

4.4.4 Hepatotoxicity
In clinical trials, more hepatic-related adverse reactions were reported in adults with the use of SIRTURO plus other drugs used to treat tuberculosis compared to other drugs used to treat tuberculosis without the addition of SIRTURO. Alcohol and other hepatotoxic drugs should be avoided while on SIRTURO, especially in patients with impaired hepatic function. Hepatic-related adverse reactions have also been reported in pediatric patients 14 to less than 18 years of age *[see Undesirable effects (4.8)]*.

Monitor symptoms (such as fatigue, anorexia, nausea, jaundice, dark urine, liver tenderness and hepatomegaly) and laboratory tests (ALT, AST, alkaline phosphatase, and bilirubin) at baseline, monthly while on treatment, and as needed. Test for viral hepatitis and discontinue other hepatotoxic medications if evidence of new or worsening liver dysfunction occurs. Discontinue SIRTURO if:
- aminotransferase elevations are accompanied by total bilirubin elevation greater than two times the upper limit of normal
- aminotransferase elevations are greater than eight times the upper limit of normal
- aminotransferase elevations are greater than five times the upper limit of normal and persist beyond two weeks

4.4.5 Drug Interactions
CYP3A4 inducers/inhibitors
Bedaquiline is metabolized by CYP3A4 and its systemic exposure and therapeutic effect may therefore be reduced during co-administration with inducers of CYP3A4. Avoid co-administration of strong CYP3A4 inducers, such as rifamycins (i.e., rifampin, rifapentine and rifabutin), or moderate CYP3A4 inducers, such as efavirenz, during treatment with SIRTURO *[see Interaction with other medicinal products and other forms of interactions (4.5.1)]*.

Co-administration of SIRTURO with strong CYP3A4 inhibitors may increase the systemic exposure to bedaquiline, which could potentially increase the risk of adverse reactions. Therefore, avoid the use of strong CYP3A4 inhibitors for more than 14 consecutive days while on SIRTURO, unless the benefit of treatment with the drug combination outweighs the risk *[see Interaction with other medicinal products*

and other forms of interactions (4.5.1)]. Appropriate clinical monitoring for SIRTURO-related adverse reactions is recommended.

4.5 Interaction with other medicinal products and other forms of interactions

4.5.1 CYP3A4 Inducers/Inhibitors

Bedaquiline exposure may be reduced during co-administration with inducers of CYP3A4 and increased during co-administration with inhibitors of CYP3A4.

CYP3A4 Inducers

Due to the possibility of a reduction of the therapeutic effect of bedaquiline because of the decrease in systemic exposure, co-administration of strong CYP3A4 inducers, such as rifamycins (i.e., rifampin, rifapentine and rifabutin), or moderate CYP3A4 inducers should be avoided during treatment with SIRTURO *[see Pharmacokinetic Properties (5.2)].*

CYP3A4 inhibitors

Due to the potential risk of adverse reactions to bedaquiline because of the increase in systemic exposure, prolonged co-administration of bedaquiline and strong CYP3A4 inhibitors, such as ketoconazole or itraconazole, for more than 14 consecutive days should be avoided unless the benefit outweighs the risk *[see Pharmacokinetic Properties (5.2)].* Appropriate clinical monitoring for SIRTURO-related adverse reactions is recommended.

4.5.2 Other Antimicrobial Medications

No dose-adjustment of isoniazid or pyrazinamide is required during co-administration with SIRTURO.

In a placebo-controlled clinical trial in adult patients with MDR-TB, no major impact of co-administration of SIRTURO on the pharmacokinetics of ethambutol, kanamycin, pyrazinamide, ofloxacin or cycloserine was observed.

4.5.3 Antiretroviral Medications

Lopinavir/ritonavir

Although clinical data in HIV/MDR-TB co-infected patients on the combined use of lopinavir (400 mg)/ritonavir (100 mg) with SIRTURO are not available, use SIRTURO with caution when co-administered with lopinavir/ritonavir and only if the benefit outweighs the risk *[see Pharmacokinetic Properties (5.2)].*

Nevirapine

No dosage adjustment of bedaquiline is required when co-administered with nevirapine *[see Pharmacokinetic Properties (5.2)].*

Efavirenz

Concomitant administration of bedaquiline and efavirenz, or other moderate CYP3A inducers, should be avoided *[see Special Warnings and Precautions (4.5.1)]*.

4.5.4 QT Interval Prolonging Drugs

In a drug interaction study of bedaquiline and ketoconazole in adults, a greater effect on QTc was observed after repeated dosing with bedaquiline and ketoconazole in combination than after repeated dosing with the individual drugs. Additive or synergistic QT prolongation was observed when bedaquiline was co-administered with other drugs that prolong the QT interval.

In Study 3, mean increases in QTc were larger in the 17 adult patients who were taking clofazimine with bedaquiline at Week 24 (mean change from reference of 31.9 ms) than in patients who were not taking clofazimine with bedaquiline at Week 24 (mean change from baseline of 12.3 ms). Monitor ECGs if SIRTURO is co-administered to patients receiving other drugs that prolong the QTc interval, and discontinue SIRTURO if evidence of serious ventricular arrhythmia or QTcF interval greater than 500 ms. *[see Special Warnings and Precautions (4.4.2) and Pharmacodynamic Properties (5.1)]*.

4.6 Pregnancy and lactation

4.6.1 Pregnancy

Risk Summary

Available data from published literature of SIRTURO use in pregnant women are insufficient to evaluate a drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes. There are risks associated with active tuberculosis during pregnancy *(see Clinical Considerations)*.

Reproduction studies performed in rats and rabbits have revealed no evidence of harm to the fetus due to oral administration of bedaquiline to pregnant rats and rabbits during organogenesis at exposures up to 6 times the clinical dose based on AUC comparisons *(see Data)*.

The estimated background risk of major birth defects and miscarriage for the indicated populations is unknown. All pregnancies have a background risk of birth defect, loss, or other adverse outcomes. In the U.S. general population, the estimated background risk of major birth defects and miscarriage in clinically recognized pregnancies is 2 to 4% and 15 to 20%, respectively.

Clinical Considerations

Disease-Associated Maternal and/or Embryo/Fetal Risk

Active tuberculosis in pregnancy is associated with adverse maternal and neonatal outcomes including maternal anemia, caesarean delivery, preterm birth, low birth weight, birth asphyxia, and perinatal infant death.

Data

Animal Data

Pregnant rats were treated with bedaquiline at 5, 15 and 45 mg/kg (approximately 0.7, 2 and 6 times the clinical dose based on AUC comparisons) during the period of organogenesis (gestational Days 6-17, inclusive). Pregnant rabbits were treated with bedaquiline at 10, 30 and 100 mg/kg (approximately 0.05, 0.2 and 1.5 times the clinical dose based on AUC comparisons) during the period of organogenesis (gestational Days 6-19, inclusive). No embryotoxic effects were found in rats or rabbits at dose exposures up to 6 times the clinical dose exposures based on AUC comparisons.

4.6.2 Lactation

Risk Summary

 Data from a published clinical lactation study demonstrate higher bedaquiline concentrations in breast milk compared to maternal plasma, suggesting that bedaquiline accumulates in breast milk (see Data). Data are insufficient to determine effects of the drug on the breastfed infants. No data are available on the effects of the drug on milk production. Because of the potential for serious adverse reactions in a breastfed infant, including hepatotoxicity, advise patients that breastfeeding is not recommended during treatment with SIRTURO and for 27.5 months (5 times the half-life) after the last dose unless infant formula is not available.

Clinical Considerations

If an infant is exposed to bedaquiline through breast milk, monitor for signs of bedaquiline-related adverse reactions, such as hepatotoxicity *[see Undesirable effects (4.8)]*.

Data

A clinical lactation study was conducted in two lactating women who were approximately 7 weeks' postpartum. Bedaquiline and M2, its active metabolite, levels were measured between approximately 27 and 48 hours after the last bedaquiline dose, and concentrations of bedaquiline and M2 ranged from 2.61 to 8.11 mg/L and 0.27 to 0.81 mg/L, respectively. The milk:plasma ratios for bedaquiline and M2 at 27 to 48 hours after the last dose of bedaquiline ranged from approximately 19 to 29 and 4 to 6, respectively.

4.7 Effect on ability to drive and use machine
Not applicable

4.8 Undesirable effects
The following serious adverse reactions are discussed elsewhere in the labeling:
- Increased mortality *[see Special Warnings and Precautions (4.4.1)]*
- QT Prolongation *[see Special Warnings and Precautions (4.4.2)* and *Pharmacodynamic Properties (5.1)]*
- Hepatotoxicity *[see Special Warnings and Precautions (4.4.4)]*
- Drug Interactions *[see Interaction with other medicinal products and other forms of interactions (4.5)]*

4.8.1 Clinical Studies Experience

Because clinical studies are conducted under widely varying conditions, adverse reaction rates observed in the clinical studies of a drug cannot be directly compared to the rates in the clinical studies of another drug and may not reflect the rates observed in clinical practice.

Use SIRTURO only in combination with other anti-mycobacterial drugs *[see Posology and method of administration (4.2.3)]*. Refer to the prescribing information of the drugs used in combination with SIRTURO for their respective adverse reactions.

Clinical Studies Experience in Adults

Adverse drug reactions for SIRTURO were identified from the pooled safety data from 335 SIRTURO-exposed patients who received 8 weeks (Study 2) and 24 weeks (Studies 1 and 3) at the proposed dose. Studies 1 and 2 were randomized, double-blind, placebo-controlled trials in newly diagnosed patients with pulmonary MDR-TB. In both treatment arms, patients received SIRTURO or placebo in combination with other drugs used to treat MDR-TB. Study 3 was an open-label, noncomparative study with SIRTURO administered as part of an individualized pulmonary MDR-TB treatment regimen in previously treated patients.

In Study 1, 35% were Black, 17.5% were Hispanic, 12.5% were White, 9.4% were Asian, and 25.6% were of another race. Eight of 79 (10.1%) patients in the SIRTURO group and 16 of 81 (19.8%) patients in the placebo treatment group were HIV-infected. Seven (8.9%) SIRTURO-treated patients and six (7.4%) placebo-treated patients discontinued Study 1 because of an adverse reaction.

Table 2: Select Adverse Reactions from Study 1 That Occurred More Frequently Than Placebo During Treatment with SIRTURO

Adverse Reactions	SIRTURO Treatment Group N=79 n (%)	Placebo Treatment Group N=81 n (%)
Nausea	30 (38)	26 (32)
Arthralgia	26 (33)	18 (22)
Headache	22 (28)	10 (12)
Hemoptysis	14 (18)	9 (11)
Chest Pain	9 (11)	6 (7)
Anorexia	7 (9)	3 (4)
Transaminases Increased[*]	7 (9)	1 (1)
Rash	6 (8)	3 (4)
Blood Amylase Increased	2 (3)	1 (1)

[*]   Terms represented by 'transaminases increased' included transaminases increased, AST increased, ALT increased, hepatic enzyme increased, and hepatic function abnormal.

No additional unique adverse reactions were identified from the uncontrolled Study 3.

In both Studies 1 and 2, aminotransferase elevations of at least 3 times the upper limit of normal developed more frequently in the SIRTURO treatment group (11/102 [10.8%] vs 6/105 [5.7%]) than in the placebo treatment group. In Study 3, 22/230 (9.6%) patients had alanine aminotransferase or aspartate aminotransferase greater than or equal to 3 times the upper limit of normal during the overall treatment period.

Increased Mortality

In Study 1, there was a statistically significant increased mortality risk by Week 120 in the SIRTURO treatment group compared to the placebo treatment group (9/79 (11.4%) versus 2/81 (2.5%), p-value=0.03, an exact 95% confidence interval of the difference [1.1%, 18.2%]). Five of the 9 SIRTURO deaths and the 2 placebo deaths were tuberculosis-related. One death occurred during the 24-week SIRTURO treatment period. The median time to death for the remaining eight patients in the SIRTURO treatment group was 329 days after last intake of SIRTURO. The imbalance in deaths is unexplained; no discernible pattern between death and sputum conversion, relapse, sensitivity to other drugs used to treat tuberculosis, HIV status, and severity of disease was observed.

In the open-label Study 3, 6.9% (16/233) of patients died. The most common cause of death as reported by the investigator was TB (9 patients). All but one patient who died of TB had not converted or had relapsed. The causes of death in the remaining patients varied.

Clinical Studies Experience in Pediatric Patients
The safety assessment of bedaquiline is based on the Week 24 analysis of the single-arm, open-label trial, TMC207-C211, in 15 pediatric patients. The trial was designed to enroll patients 12 to less than 18 years of age (only patients 14 to less than 18 years of age were enrolled) with confirmed or probable pulmonary MDR-TB infection who received SIRTURO at the recommended dosage regimen in combination with a background regimen [see Clinical Studies].

The most common adverse drug reactions were arthralgia in 6/15 (40%) patients, nausea in 2/15 (13%) patients, and abdominal pain in 2/15 (13%) patients. Among the 15 patients, no deaths occurred during treatment with SIRTURO. Observed laboratory abnormalities were comparable to those in adults.

4.9 Overdose

There is no experience with the treatment of acute overdose with SIRTURO. Take general measures to support basic vital functions including monitoring of vital signs and ECG (QT interval) in case of deliberate or accidental overdose. It is advisable to contact a poison control center to obtain the latest recommendations for the management of an overdose. Since bedaquiline is highly protein-bound, dialysis is not likely to significantly remove bedaquiline from plasma.

5 Pharmacological Properties
Mechanism of Action
Bedaquiline is a diarylquinoline antimycobacterial drug [see Microbiology].

5.1Pharmacodynamic Properties

Bedaquiline is primarily subjected to oxidative metabolism leading to the formation of *N*-monodesmethyl metabolite (M2). M2 is not thought to contribute significantly to clinical efficacy given its lower average exposure (23% to 31%) in humans and lower antimycobacterial activity (4-fold to 6-fold lower) compared to the parent compound. However, M2 plasma concentrations appeared to correlate with QT prolongation.

Cardiac Electrophysiology

In Study 1, in adults, the mean increases in QTcF, corrected using the Fridericia method, were greater in the SIRTURO treatment group compared to the placebo treatment group from the first week of treatment (9.9 ms at Week 1 for SIRTURO and 3.5 ms for placebo). The largest mean increase in QTcF during the 24 weeks of SIRTURO treatment was 15.7 ms compared to 6.2 ms with placebo treatment (at Week 18). After bedaquiline treatment ended, the QTcF gradually decreased, and the mean value was similar to that in the placebo group by study week 60.

In Study 3, where adult patients with no treatment options received other QT-prolonging drugs used to treat tuberculosis, including clofazimine, concurrent use with SIRTURO resulted in additive QTcF prolongation, proportional to the number of QT prolonging drugs in the treatment regimen. Patients taking SIRTURO alone with no other QT prolonging drug developed a mean QTcF increase over baseline of 23.7 ms with no QTcF segment duration in excess of 480 ms, whereas patients taking at least 2 other QT prolonging drugs developed a mean QTcF prolongation of 30.7 ms over baseline, and resulted in QTcF segment duration in excess of 500 ms in one patient. *[see Special Warnings and Precautions (4.4.2)]*

CLINICAL STUDIES

5.1.1 Adult Patients

A placebo-controlled, double-blind, randomized trial (Study 1) was conducted in patients with newly diagnosed sputum smear-positive MDR pulmonary *M. tuberculosis*. All patients received a combination of five other antimycobacterial drugs used to treat MDR-TB (i.e., ethionamide, kanamycin, pyrazinamide, ofloxacin, and cycloserine/terizidone or available alternative) for a total duration of 18-24 months or at least 12 months after the first confirmed negative culture. In addition to this regimen, patients were randomized to receive 24 weeks of treatment with SIRTURO 400 mg once daily for the first 2 weeks followed by 200 mg 3 times per week for 22 weeks or matching placebo for the same duration. Overall, 79 patients were randomized to the SIRTURO arm and 81 to the placebo arm. A final evaluation was conducted at Week 120.

Sixty-seven patients randomized to SIRTURO and 66 patients randomized to placebo had confirmed MDR-TB, based on susceptibility tests (taken prior to randomization) or medical history if no susceptibility results were available, and were included in the efficacy

analyses. Demographics were as follows: 63% of the study population was male, with a median age of 34 years, 35% were Black, and 15% were HIV-positive (median CD4 cell count 468 cells/μL). Most patients had cavitation in one lung (62%); and 18% of patients had cavitation in both lungs.

Time to sputum culture conversion was defined as the interval in days between the first dose of study drug and the date of the first of two consecutive negative sputum cultures collected at least 25 days apart during treatment. In this trial, the SIRTURO treatment group had a decreased time to culture conversion and improved culture conversion rates compared to the placebo treatment group at Week 24. Median time to culture conversion was 83 days for the SIRTURO treatment group compared to 125 days for the placebo treatment group. Table 3 shows the proportion of patients with sputum culture conversion at Week 24 and Week 120.

Table 3: Culture Conversion Status in Patients with MDR-TB at Week 24 and Week 120 in Study 1

Microbiologic Status	SIRTURO (24 weeks) + combination of other antimycobacterial drugs N=67	Placebo (24 weeks) + combination of other antimycobacterial drugs N=66	Difference [95% CI] p-value
Week 24			
Sputum Culture Conversion	78%	58%	20.0% [4.5%, 35.6%] 0.014
Treatment failure*	22%	42%	
Died	1%	0%	
Lack of conversion	21%	35%	
Discontinuation	0%	8%	
Week 120**			
Sputum Culture Conversion	61%	44%	17.3% [0.5%, 34.0%] 0.046
Treatment failure*	39%	56%	
Died	12%	3%	
Lack of conversion/relapse	16%	35%	
Discontinuation	10%	18%	

* A patient's reason for treatment failure was counted only in the first row for which a patient qualifies.
** Patients received 24 weeks of SIRTURO or placebo for the first 24 weeks and received a combination of other antimycobacterial drugs for up to 96 weeks.

Study 2 was a smaller placebo-controlled study designed similarly to Study 1 except that SIRTURO or placebo was given for only 8 weeks instead of 24 weeks. Patients were randomized to either SIRTURO and other drugs used to treat MDR-TB (SIRTURO

treatment group) (n=23) or placebo and other drugs used to treat MDR-TB (placebo treatment group) (n=24). Twenty-one patients randomized to the SIRTURO treatment group and 23 patients randomized to the placebo treatment group had confirmed MDR-TB based on patients' baseline *M. tuberculosis* isolate obtained prior to randomization. The SIRTURO treatment group had a decreased time to culture conversion and improved culture conversion rates compared to the placebo treatment group at Week 8. At Weeks 8 and 24, the differences in culture conversion proportions were 38.9% (95% CI: [12.3%, 63.1%] and p-value: 0.004), 15.7% (95% CI: [-11.9%, 41.9%] and p-value: 0.32), respectively.

Study 3 was a Phase 2b, uncontrolled study to evaluate the safety, tolerability, and efficacy of SIRTURO as part of an individualized MDR-TB treatment regimen in 233 patients with sputum smear positive (within 6 months prior to screening) pulmonary MDR-TB. Patients received SIRTURO for 24 weeks in combination with antibacterial drugs. Upon completion of the 24 week treatment with SIRTURO, all patients continued to receive their background regimen in accordance with national TB program (NTP) treatment guidelines. A final evaluation was conducted at Week 120. Treatment responses to SIRTURO at week 120 were generally consistent with those from Study 1.

5.1.2 Pediatric Patients (12 to less than 18 years of age)

The pediatric trial, TMC207-C211(NCT02354014), was designed as a single-arm, open-label, trial to evaluate the pharmacokinetics, safety and tolerability of SIRTURO in combination with a background regimen in patients 12 to less than 18 years of age with confirmed or probable pulmonary MDR-TB infection. Fifteen patients ages 14 to less than 18 years of age were enrolled in the study. The median age was 16 years, 80% were female, 53% were Black, 33% were White and 13% were Asian. No patient 12 to less than 14 years of age was enrolled in the study. SIRTURO was administered as 400 mg once daily for the first 2 weeks and 200 mg 3 times/week for the following 22 weeks.

In the subset of patients with culture positive pulmonary MDR-TB at baseline, treatment with bedaquiline resulted in conversion to a negative culture in 75.0% (6/8 patients) at Week 24.

5.2 Pharmacokinetic Properties

The pharmacokinetic parameters of bedaquiline in adult MDR-TB patients at the recommended dosing regimen of SIRTURO (400 mg for 2 weeks followed by 200 mg three times per week for 22 weeks) in combination with a background regimen are provided in Table 4.

Table 4: Pharmacokinetic Parameters of Bedaquiline Following Repeat Dose Administration of SIRTURO at the Recommended Dosing Regimen to Adult MDR-TB Patients at Week 8 Administered with Food (N = 18)

Pharmacokinetic Parameter	Bedaquiline Mean (SD)
AUC_{24h} (ng•h/mL)	25,863 (13,259)
C_{max} (ng/mL)	1,659 (722)
T_{max} (h)*	5 (3-8)
C_{min} (ng/mL)	654 (498)
SD=Standard deviation * Median (range)	

Absorption

After single oral dose administration of SIRTURO, maximum plasma concentrations (C_{max}) are typically achieved at approximately 5 hours post-dose. C_{max} and the area under the plasma concentration-time curve (AUC) increased proportionally up 700 mg (1.75 times the 400 mg loading dose).

Administration of SIRTURO with a standard meal containing approximately 22 grams of fat (558 total Kcal) increased the relative bioavailability by approximately 2-fold compared to administration under fasted conditions. SIRTURO should be taken with food to enhance its oral bioavailability.

Distribution

The plasma protein binding of bedaquiline is greater than 99.9%. The volume of distribution in the central compartment is estimated to be approximately 164 Liters.

Elimination

After reaching C_{max}, bedaquiline concentrations decline tri-exponentially. The mean terminal elimination half-life of bedaquiline and the *N*-monodesmethyl metabolite (M2) is approximately 5.5 months. This long terminal elimination phase likely reflects slow release of bedaquiline and M2 from peripheral tissues.

Metabolism

CYP3A4 was the major CYP isoenzyme involved in the *in vitro* metabolism of bedaquiline and the formation of the *N*-monodesmethyl metabolite (M2).

Excretion

Based on preclinical studies, bedaquiline is mainly excreted in feces. The urinary excretion of unchanged bedaquiline was less than or equal to 0.001% of the dose in clinical studies, indicating that renal clearance of unchanged drug is insignificant.

Specific Populations

Hepatic Impairment: After single-dose administration of 400 mg SIRTURO to 8 adult patients with moderate hepatic impairment (Child-Pugh B), mean exposure to bedaquiline and M2 (AUC_{672h}) was approximately 20% lower compared to healthy subjects. SIRTURO

has not been studied in patients with severe hepatic impairment. *[See Special Warnings and Precautions (4.4.4) and Hepatic impairment (4.2.6)]*.

Renal Impairment: SIRTURO has mainly been studied in adult patients with normal renal function. Renal excretion of unchanged bedaquiline is not substantial (less than or equal to 0.001%).

In a population pharmacokinetic analysis of MDR-TB adult patients treated with SIRTURO 200 mg three times per week, creatinine clearance was not found to influence the pharmacokinetic parameters of bedaquiline. It is therefore not expected that mild or moderate renal impairment will have a clinically relevant effect on the exposure to bedaquiline. However, in patients with severe renal impairment or end-stage renal disease requiring hemodialysis or peritoneal dialysis bedaquiline concentrations may be increased due to alteration of drug absorption, distribution, and metabolism secondary to renal dysfunction. As bedaquiline is highly bound to plasma proteins, it is unlikely that it will be significantly removed from plasma by hemodialysis or peritoneal dialysis *[see Renal impairment (4.2.7)]*.

Sex: In a population pharmacokinetic analysis of MDR-TB adult patients treated with SIRTURO no clinically relevant difference in exposure between men and women were observed.

Race/Ethnicity: In a population pharmacokinetic analysis of MDR-TB adult patients treated with SIRTURO, systemic exposure (AUC) to bedaquiline was found to be 34% lower in Black patients than in patients from other race categories. This lower exposure was not considered to be clinically relevant as no clear relationship between exposure to bedaquiline and response has been observed in clinical trials of MDR-TB. Furthermore, response rates were comparable in patients of different race categories that completed 24 weeks of bedaquiline treatment.

HIV Co-infection: There are limited data on the use of SIRTURO in HIV co-infected patients *[see Interaction with other medicinal products and other forms of interactions (4.5)]*.

Geriatric Population: There are limited data on the use of SIRTURO in tuberculosis patients 65 years of age and older.

In a population pharmacokinetic analysis of MDR-TB adult patients treated with SIRTURO, age was not found to influence the pharmacokinetics of bedaquiline.

Pediatric Population: The pharmacokinetic parameters of bedaquiline in 15 MDR-TB pediatric patients 14 to less than 18 years of age who received the same adult dosage regimen of SIRTURO (400 mg once daily for the first 2 weeks and 200 mg 3 times/week for the following 22 weeks) in combination with a background regimen were comparable to those in adults; see Table 5 below for a summary of the pharmacokinetic parameters.

There was no impact of body weight on bedaquiline pharmacokinetics in pediatric MDR-TB patients 14 to less than 18 years of age (38 to 75 kg).

Table 5: Pharmacokinetic Parameters of Bedaquiline Following Repeat Dose Administration of SIRTURO to Pediatric MDR-TB Patients 14 to less than 18 years of age at Week 12 Administered with Food (N=15)

Pharmacokinetic Parameter	Bedaquiline Mean (SD)
AUC_{24h} (ng•h/mL)	26,300 (10,300)
C_{max} (ng/mL)	1,800 (736)
T_{max} (h)*	4 (2-8)
C_{min} (ng/mL)	544 (263)
SD=Standard Deviation	
* Median (range)	

The pharmacokinetics of SIRTURO in pediatric patients less than 14 years of age or weighing less than 38 kg have not been evaluated.

Drug-Drug Interactions

In vitro, bedaquiline does not significantly inhibit the activity of the following CYP450 enzymes that were tested: CYP1A2, CYP2A6, CYP2C8/9/10, CYP2C19, CYP2D6, CYP2E1, CYP3A4, CYP3A4/5 and CYP4A, and it does not induce CYP1A2, CYP2C9, CYP2C19, or CYP3A4 activities.

Bedaquiline is an *in vitro* substrate of CYP3A4, and because of this, the following clinical drug interaction studies were performed.

Ketoconazole: Co-administration of multiple-dose bedaquiline (400 mg once daily for 14 days) and multiple-dose ketoconazole (once daily 400 mg for 4 days) in healthy adult subjects increased the AUC_{24h}, C_{max} and C_{min} of bedaquiline by 22% [90% CI (12; 32)], 9% [90% CI (-2, 21)] and 33% [90% CI (24, 43)] respectively *[see Interaction with other medicinal products and other forms of interactions (4.5.1) (4.5.4)]*.

Rifampin: In a drug interaction study of single-dose 300 mg bedaquiline and multiple-dose rifampin (once daily 600 mg for 21 days) in healthy adult subjects, the exposure (AUC) to bedaquiline was reduced by 52% [90% CI (-57; -46)] *[see Interaction with other medicinal products and other forms of interactions (4.5.1)]*

Antimicrobial agents: The combination of multiple-dose bedaquiline 400 mg once daily with multiple-dose isoniazid/pyrazinamide (300 mg/2000 mg once daily) in healthy adult subjects did not result in clinically relevant changes in the exposure (AUC) to bedaquiline, isoniazid or pyrazinamide *[see Interaction with other medicinal products and other forms of interactions (4.5.2)]*

In a placebo-controlled study in adult patients with MDR-TB, no major impact of co-administration of bedaquiline on the pharmacokinetics of ethambutol, kanamycin,

pyrazinamide, ofloxacin or cycloserine was observed.

Lopinavir/ritonavir: In a drug interaction study in healthy adult volunteers of single-dose bedaquiline (400 mg) and multiple-dose lopinavir (400 mg)/ritonavir (100 mg) given twice daily for 24 days, the mean AUC of bedaquiline was increased by 22% [90% CI (11; 34)] while the mean C_{max} was not substantially affected *[see Interaction with other medicinal products and other forms of interactions (4.5.3)]*

Nevirapine: Co-administration of multiple-dose nevirapine 200 mg twice daily for 4 weeks in HIV-infected adult patients with a single 400 mg dose of bedaquiline did not result in clinically relevant changes in the exposure to bedaquiline *[see Interaction with other medicinal products and other forms of interactions (4.5.3)]*

Efavirenz: Co-administration of a single dose of bedaquiline 400 mg and efavirenz 600 mg daily for 27 days to healthy adult volunteers resulted in approximately a 20% decrease in the AUC_{inf} of bedaquiline; the C_{max} of bedaquiline was not altered. The AUC and C_{max} of the primary metabolite of bedaquiline (M2) were increased by 70% and 80%, respectively. The effect of efavirenz on the pharmacokinetics of bedaquiline and M2 following steady-state administration of bedaquiline has not been evaluated *[see Interaction with other medicinal products and other forms of interactions (4.5.3)]*

Microbiology

Mechanism of Action

SIRTURO is a diarylquinoline antimycobacterial drug that inhibits mycobacterial ATP (adenosine 5'-triphosphate) synthase, by binding to subunit c of the enzyme that is essential for the generation of energy in *M. tuberculosis*.

Resistance

A potential for development of resistance to bedaquiline in *M. tuberculosis* exists. Modification of the *atpE* target gene, and/or upregulation of the MmpS5-MmpL5 efflux pump (*Rv0678* mutations) have been associated with increased bedaquiline MIC values in isolates of *M. tuberculosis*. Target-based mutations generated in preclinical studies lead to 8- to 133-fold increases in bedaquiline MIC, resulting in MICs ranging from 0.25 to 4 micrograms per mL. Efflux-based mutations have been seen in preclinical and clinical isolates. These lead to 2- to 8-fold increases in bedaquiline MICs, resulting in bedaquiline MICs ranging from 0.25 to 0.5 micrograms per mL.

M. tuberculosis isolates from a clinical study in adult patients with MDR-TB that developed at least 4-fold increase in bedaquiline MIC were associated with mutations in Rv0678 gene that lead to upregulation of the MmpS5-MmpL5 efflux pump. Isolates with these efflux-based mutations are less susceptible to clofazimine. Isolates that are phenotypically resistant to bedaquiline should be tested for cross-resistance to clofazimine, if clofazimine is being considered as part of the treatment regimen. In the Phase II trials there was no

clear relationship between the presence of *Rv0678* mutations at baseline and treatment outcome.

Activity *In Vitro* and in Clinical Infections

SIRTURO has been shown to be active *in vitro* and in clinical infections against most isolates of *M. tuberculosis [see Therapeutic Indication (4.1)* and *Clinical Studies]*.

Susceptibility Testing

The bedaquiline agar (left) and resazurin microtiter assay (REMA; a 7H9 broth microdilution to which resazurin, a bacterial growth indicator, was added) (right) MIC distributions against clinical isolates resistant to isoniazid and rifampin from Studies 1, 2, and 3 are provided below.

Figure 1: Bedaquiline MIC Distribution against Baseline MDR$_{H\&R}$-TB Isolates from Studies 1, 2, and 3 mITT Adult Patients: Agar Method (left) and Broth (REMA) Method (right)

MICs for baseline *M. tuberculosis* isolates from patients in Studies 1 and 3 and their sputum culture conversion rates at Week 24 are shown in Table 6 below. Based on the available data, there was no trend for poor microbiologic outcomes related to baseline bedaquiline MIC.

Table 6:   Culture Conversion Rates (Week 24 Data Selection, No Overruling for Discontinuation) at Week 24 By Baseline Bedaquiline MIC for mITT Patients from Study 1 and Study 3

Baseline Bedaquiline MIC (micrograms/mL)	SIRTURO (Bedaquiline) Treatment Group 24-Week Culture Conversion Rate n/N (%)	
	7H11 Agar	7H9 Broth (REMA)
≤ 0.008	2/2 (100)	21/25 (84.0)
0.015	13/15 (86.7)	33/39 (84.6)
0.03	36/46 (78.3)	70/92 (76.1)
0.06	82/107 (76.6)	45/56 (80.4)
0.12	36/42 (85.7)	6/7 (85.7)
0.25	3/4 (75.0)	3/4 (75.0)
0.5	5/6 (83.3)	0/1 (0)
≥ 1	0/1 (0)	

N=number of patients with data; n=number of patients with that result; MIC=minimum inhibitory concentration; BR=background regimen

Nineteen patients in the efficacy population of study 3 had bedaquiline susceptibility testing results of paired (baseline and post-baseline, all of which were at Week 24 or later) genotypically identical isolates. Twelve of the 19 had a post-baseline ≥4-fold increase in bedaquiline MIC. Whole genome sequencing of 9 of these 12 post-baseline isolates was done and no mutations were found in the ATP synthase operon. All 9 were found to have a mutation in *Rv0678*. Eleven of the twelve (11/12) increases in bedaquiline MIC were seen in patients with pre-XDR-TB or with XDR-TB. Pre-XDR-TB is defined as MDR-TB isolates resistant to either a fluoroquinolone or a second line injectable drug, and XDR-TB as MDR-TB isolates resistant to both a fluoroquinolone and a second line injectable drug. Based on available data, response rate (culture conversion at week 120 endpoint) was similar in patients with ≥4-fold increases in bedaquiline MIC (5/12) and patients with < 4-fold increases (3/7).

For specific information regarding susceptibility test criteria and associated test methods and quality control standards recognized by FDA for this drug, please see: *www.fda.gov/STIC*.

5.3 Preclinical Safety Data

5.3.1   Carcinogenesis, Mutagenesis, and Impairment of Fertility

Bedaquiline was not carcinogenic in rats up to the maximum tolerated dose of 10 mg/kg/day. Exposures at this dose in rats (AUCs) were within 1-fold to 2-fold of those observed in adult patients in the clinical trials.

No mutagenic or clastogenic effects were detected in the *in vitro* non-mammalian reverse mutation (Ames) test, *in vitro* mammalian (mouse lymphoma) forward mutation assay and an *in vivo* mouse bone marrow micronucleus assay.

SIRTURO did not affect fertility when evaluated in male and female rats at approximately twice the clinical exposure based on AUC comparisons. There was no effect of maternal

treatment on sexual maturation, mating performance or fertility in F1 generation exposed to bedaquiline *in utero* at approximately twice the human exposure.

5.3.2 Animal Toxicology and/or Pharmacology

Bedaquiline is a cationic, amphiphilic drug that induced phospholipidosis (at almost all doses, even after very short exposures) in drug-treated animals, mainly in cells of the monocytic phagocytic system (MPS). All species tested showed drug-related increases in pigment-laden and/or foamy macrophages, mostly in the lymph nodes, spleen, lungs, liver, stomach, skeletal muscle, pancreas and/or uterus. After treatment ended, these findings were slowly reversible. Muscle degeneration was observed in several species at the highest doses tested. For example, the diaphragm, esophagus, quadriceps and tongue of rats were affected after 26 weeks of treatment at doses similar to clinical exposures based on AUC comparisons. These findings were not seen after a 12-week, treatment-free, recovery period and were not present in rats given the same dose biweekly. Degeneration of the fundic mucosa of the stomach, hepatocellular hypertrophy and pancreatitis were also seen.

6 Pharmaceutical Particulars

6.1 List of excipients
colloidal silicon dioxide, corn starch, croscarmellose sodium, hypromellose 2910 15 mPa.s, lactose monohydrate, magnesium stearate, microcrystalline cellulose, polysorbate 20, purified water (removed during processing).

6.2 Incompatibilities
Not applicable

6.3 Shelf life
See outer carton

6.4 Special precautions for storage
Dispense in original container. Store tablets dispensed outside the original container in a tight light-resistant container with an expiration date not to exceed 3 months.
Do not store above 30°C. See expiry date on the outer pack.
Keep out of reach of children.

6.5 Nature and contents of container
SIRTURO is supplied as uncoated white to almost white round biconvex 100 mg tablets with debossing of "T" over "207" on one side and "100" on the other side. The tablets are packaged in white high density polyethylene (HDPE) bottles with child-resistant polypropylene (PP) closure with induction seal liner. Each bottle contains 188 tablets.

To report Suspected Adverse Reactions, please contact us at aepqcjacth@its.jnj.com

For any product information, please contact us at medinfosea@its.jnj.com

PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide).

Serious Adverse Reactions

Advise patients that the following serious side effects can occur with SIRTURO: death, heart rhythm abnormalities, and/or hepatitis. In addition, advise patients about other potential side effects: nausea, joint pain, headache, increased blood amylase, hemoptysis, chest pain, anorexia, rash, and/or abdominal pain. Additional testing may be needed to monitor or reduce the likelihood of adverse effects.

Compliance with Treatment

Advise patients to take SIRTURO in combination with other antimycobacterial drugs as prescribed. Emphasize compliance with the full course of therapy. Advise patients that skipping doses or not completing the full course of therapy may (1) decrease the effectiveness of the treatment and (2) increase the likelihood that their mycobacterium may develop resistance and the disease will not be treatable by SIRTURO or other antibacterial drugs in the future.

If a dose is missed during the first 2 weeks of treatment, advise patients not to make up the missed dose but to continue the usual dosing schedule. From Week 3 onwards, if a 200 mg dose is missed, advise patients to take the missed dose as soon as possible, and then resume the 3 times a week regimen.

Administration Instructions

Inform patients to take SIRTURO with food.

Use with Alcohol and other Medications

Advise patients to abstain from alcohol, hepatotoxic medications or herbal products.

Advise patients to discuss with their physician the other medications they are taking and other medical conditions before starting treatment with SIRTURO.

Lactation

Advise patients not to breastfeed during treatment with SIRTURO and for 27.5 months after the last dose unless infant formula is not available. If an infant is exposed to bedaquiline through breast milk, advise caregivers to monitor the infant for signs of bedaquiline-related adverse reactions, such as hepatotoxicity (yellowing of the eyes and changes in the color of the urine or stool) *[see Undesirable effects (4.8) and Pregnancy and lactation (4.6)]*.
